July 2024

1 Introduction

The Google scraper allows you to extract search results from Google for a specific website within a defined date range.

2 Requirements

To use this program, you must first install the required libraries listed in the 'requirements.txt' file. The program uses Selenium with the Chrome WebDriver, so you need to download the ChromeDriver before use. You can download it from the following link: [Chrome WebDriver](#). For newer versions of Chrome, it can be downloaded here: [Chrome for testing](#) (scroll down). Instructions on getting started (esp. python finding the executable) are here.

3 How to Use the Scraper

Open the 'main.py' file to specify the domain of the website from which you want to obtain Google search results. You can also define the start and end dates for your search. Then, run the program by executing 'main.py' in the terminal, and the scraping process will begin.

4 Points of Attention

When you first run the program, you will need to accept cookies. During the scraping process, you may be required to solve a CAPTCHA. The program is designed to wait until the CAPTCHA is solved, so you should be available to handle this during scraping.
